Soil Drought

Pupil sheet

Name: _____ **Date:** _____

Safety: No measuring in the rain; the box and the laptop stay dry; I wash my hands after touching soil.

1. What I see on the screen

On the screen I see the **soil moisture** in per cent: 0 % is the probe in air, 100 % the probe in water. Each **Measure** writes one row: the average of five readings.

My calibration: on _____ air _____ water _____ Days since the last rain: _____

Three rules. I push the probe in **up to its line**, with no stone against it. I wipe it before each new spot. I type the place and the depth the same way every time.

2. What I do on my own

First I predict. I do not change my prediction after I measure.
The driest place will be: _____
At the surface the soil will be: ☐ drier ☐ wetter ☐ the same as at 10 cm.
My measurements (soil moisture, in %).

Place	Depth (cm)	1	2	3	Average
A _____					
A					
B _____					
B					
C _____					
C					
D _____					
D					

Average = (1 + 2 + 3) ÷ 3. Example: (18 + 22 + 20) ÷ 3 = 20 %.
In Excel: the averages in one column per depth, then *Insert* → *Column chart*: one group of

bars for each place.

3. The conclusion I write

I predicted that, and the data show that _____

_____

The places in order, from the driest: _____, _____, _____

I think this place is driest because _____

_____

The limit of our measurement: is the difference between two places larger than the spread of the three repeats?

_____

Exit ticket

If it does not rain for two more weeks, where in our grounds will a plant suffer first, and what in your data tells you so?

_____
