

Measurement Notebook

Student sheet

Name: _____

Date: _____

1. What I see on the screen

The window is called **Measurement Logbook**, although the card reads **Measurement Notebook** — it is the same thing. At the top: the **Quantity:** list, empty for the first few seconds, then ordered **by the sensor's code, not alphabetically** — **Temperature** is near the end of the list. Beside it, the label field; **Enter** saves it, the same as the green **Save the value** button. The big blue number is the live value, **not yet saved**. Below: **Delete last**, **Clear all** (*deletes everything — does not ask and cannot be undone!*) and **Export CSV**. **One quantity per session:** changing the list does not delete the points, but it ruins the file's header. **Wait 60 s at every stop** (90 s for CO₂, 5 s for light), stand still, hold the box by its edges and do not breathe towards it. **Export before closing the window.**

2. What I do on my own

Protocol (circle one): 1 heat map / 2 light map / 3 CO₂ across spaces **Box:** _____

Quantity chosen: _____ **Unit:** _____ **Height:** _____ m **Start time:** _____

The exported file will be called: _____

First I predict. I do not change my prediction after I measure. The highest value will be at _____, the lowest at _____, and the difference between them will be _____, because _____

The labels. I copy them from here, letter by letter. Rules: (1) lower-case letters only; (2) no accented letters (naive, not naïve); (3) a hyphen, not a space; (4) at most three words; (5) only from the list; (6) **never leave the field empty** — the app writes #1, #2 on its own, and those can no longer be grouped.

1. **Heat map** (8 stops, **Temperature**): 1 door · 2 front-left-corner · 3 teacher-desk · 4 front-right-corner · 5 centre · 6 window · 7 radiator · 8 back-corner

2. **Light map** (9 stops, **Illuminance**): 1 desk-1-window · 2 desk-1-middle · 3 desk-1-door · 4 desk-3-window · 5 desk-3-middle · 6 desk-3-door · 7 desk-5-window · 8 desk-5-middle · 9 desk-5-door

3. **CO₂ across spaces** (7 stops, **CO2**): 1 outside · 2 empty-room · 3 occupied-room · 4 corridor-break · 5 library · 6 sports-hall · 7 outside-return

Now I measure. Row n is stop n from the list above. **The circuit is walked twice**, in the same order.

#	Label	Time	Circ. 1	Circ. 2	Conditions
1					
2					
3					
4					
5					
6					
7					
8					
9					

The threshold: how big a difference has to be before I believe it.

Spread = the biggest Circ. 2 – Circ. 1 difference at the same place: _____ **Drift** = stop 1: _____ – _____ = _____

Threshold = spread + drift; e.g. $0.3 + 0.5 = 0.8$. Mine: _____ + _____ = _____

Highest: _____ Lowest: _____ Difference: _____, which ☐ **is** ☐ **is not** bigger than the threshold. *“Not detected” does not mean “does not exist”.*

3. The conclusion I write

I predicted that, and the data show that _____

The difference I trust is, because _____

For someone else to repeat our measurement, we would need to give them _____

Exit ticket

One thing that surprised you today, and one thing you would do differently if you repeated the measurement.
